## Download and Installation

- The VBM8 Toolbox runs within SPM8. That is, SPM8 needs to be installed and added to your Matlab search path before the VBM8 Toolbox can be installed (see <http://www.fil.ion.ucl.ac.uk/spm/> and <http://en.wikibooks.org/wiki/SPM>).
- Download (<http://dbm.neuro.uni-jena.de/vbm8/>) and unzip the VBM8 Toolbox. You will get a folder named “vbm8”, which contains various matlab files and compiled scripts. Copy the folder “vbm8” into the SPM8 “toolbox” folder.

## Starting the Toolbox

- Start Matlab
- Start SPM8 (i.e., type “spm\_fmri”)
- Select “vbm8” from the SPM menu (see Figure 1). You will find the drop-down menu between the “Display” and the “Help” button. This will open the VBM8 Toolbox (in SPM’s 2nd window). You can access the VBM8 Toolbox menu by clicking on “VBM8” (located at the upper left corner of this window; see Figure 2).

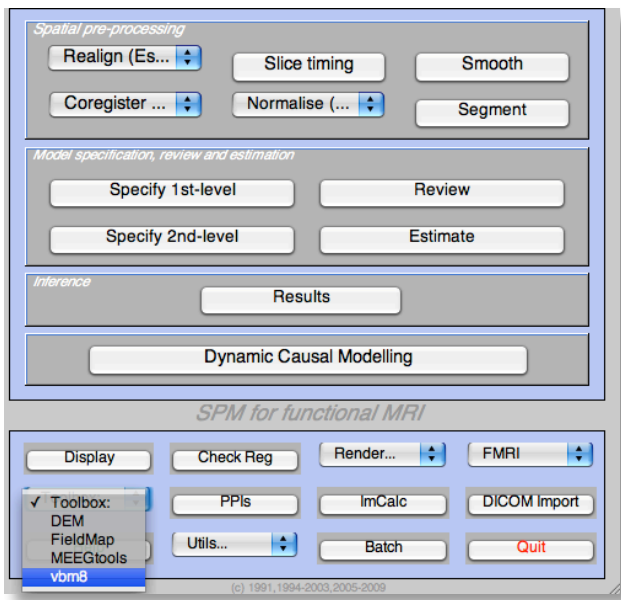

Figure 1: SPM menu

Figure 2: SPM’s 2<sup>nd</sup> window with the VBM8 Toolbox menu

## ***Basic VBM analysis (overview)***

The VBM8 Toolbox comes with different modules, which may be used for an analysis. Usually, a VBM analysis comprises the following steps:

### **(a) Preprocessing:**

1. T1 images are **normalized** to a template space and **segmented** into gray matter (GM), white matter (WM) and cerebrospinal fluid (CSF). The preprocessing parameters can be adjusted via the module “Estimate and write”.
2. After the preprocessing is finished, a **quality check** is highly recommended. This can be achieved via the modules “Display one slice for all images” and “Check sample homogeneity using covariance”. Both options are located under “VBM8 → Check data quality”.
3. Before entering the GM images into a statistical model, image data need to be **smoothed**. Of note, this step is not implemented into the VBM8 Toolbox but achieved via the standard SPM module “Smooth”.

### **(b) Statistical analysis:**

4. The smoothed GM images are entered into a statistical analysis. This requires building a statistical model (e.g., T-Tests, ANOVAs, multiple regressions). This is done by the standard SPM modules “Specify 2nd Level”.
5. The statistical model is estimated. This is done by the standard SPM module “Estimate”.
6. After estimating the statistical model, contrasts will be defined to get the results of the analysis. This is done by the standard SPM module “Results”.

### ***A few words about the Batch Editor...***

- As soon as you select a module from the VBM8 Toolbox menu, a new window (the Batch Editor) will open. The Batch Editor is the environment where you will set up your analysis (see **Figure 3**). For example, an “<-X” indicates where you need to select files (e.g., your image files, the template, etc.). Other parameters have either default settings (which can be modified) or require input (e.g., choosing between different options, providing text or numeric values, etc.).
- Once all missing parameters are set, a green arrow will appear on the top of the window (the current snapshots in **Figure 3** show the arrow still in gray). Click this arrow to run the module or select “File → Run Batch”. It is very useful to save the settings before you run the batch (click on the disk symbol or select “File → Save Batch”).
- Of note, you can always find helpful information and parameter-specific explanations at the bottom of the Batch Editor window.<sup>1</sup>

---

<sup>1</sup> Additional VBM8-related information can be found by selecting “VBM Tools website” in the VBM8 Toolbox menu. This will open a website. Here, look for “VBM subpages” on the right.

- All settings can be saved either as .mat file or as .m script file and reloaded for later use. The .m script file has the advantage to be editable with a text editor.

**Figure 3:** The Batch Editor is the environment where the analysis is set up. *Left:* For all settings marked with “<-X”, files have to be selected (“Select Files”). *Right:* Parameters can be edited and adapted (“Edit Value”).

## Basic VBM analysis (detailed description)

1. Select your working directory.  
Before running anything, it is recommended to always set SPM’s working directory: “Utilities → CD” (right to the “Help” button in the SPM main menu). Select your working directory and click “Done” to change the directory.
2. Open the VBM Toolbox.
3. Select the module you want to run.
4. Specify the parameters (see below).
5. Run the module.

Of note, for debugging, the relevant information can be printed by selecting “Print VBM debug information” from the VBM8 Toolbox menu.

## Modules

---

### FIRST MODULE: ESTIMATE AND WRITE

---

#### VBM8 → Estimate and write

Parameters:

- Volumes <-X → Select Files → *[select raw data]* → Done
  - Select one volume for each subject. As the Toolbox does not support multispectral data yet (i.e., different imaging methods for the same brain, such as T1-, T2-, diffusion-weighted or CT images), it is recommended to choose a T1-weighted image.
  - Importantly, the images need to be in the same orientation as the template and priors; you can double-check and correct via using “Display” in the SPM menu. By default the MNI template is used (located in your SPM folder “spm8 → templates → T1”)
- Estimation Options → *[use defaults or modify]*
  - The defaults provide a solid starting point for the analysis. If you prefer to use your own customized Tissue Probability Maps (TPMs), you can specify / select them here. However, the new segmentation approach in VBM8 does not need tissue priors for the segmentation anymore. Customized TPMs will be only used for the spatial normalization. Thus, creating your own TPMs might be only appropriate for children’s data if they largely deviate from the standard MNI template. In order to create your own TPMs the Template-O-Matic (TOM8) Toolbox can be used.
- Extended Options → *[use defaults or modify]*
  - Again, the defaults provide a solid starting point. The high-dimensional DARTEL normalization is used as the default spatial normalization. Alternatively, the low-dimensional SPM8 spatial normalization can be chosen. Furthermore, remaining non-brain tissue can be removed more thoroughly by setting the option “Clean up any partitions” to “Thorough Cleanup”. This is particularly useful for very atrophic brains (e.g., as occurring in Alzheimer’s disease).
- Writing Options → *[use defaults or modify]*
  - For **GM, WM, and CSF image volumes** see page 14: “Additional Information on native, normalized and modulated normalized volumes”. Note: *The default option “Modulated normalized – non linear only” will result in an analysis of relative differences in regional GM volume, corrected for individual brain size.*
  - A **bias corrected image volume**, in which MRI inhomogeneities and noise are removed, can be written in normalized or native space. This is useful for quality control and also to create an average image of all normalized T1

images in order to display / overlay the results. *Note: For a basic VBM analysis use the defaults.*

- A **partial volume effect (PVE) label image volume** can also be written in normalized or native space or as a DARTEL export file. This is useful for quality control and also for future applications using this image to reconstruct surfaces. *Note: For a basic VBM analysis use the defaults.*
- The **Jacobian determinant** for each voxel can be written in normalized space. This information can be used to do a Tensor-Based Morphometry (TBM) analysis. *Note: For a basic VBM analysis this is not needed.*
- Finally, **deformation fields** can be written. This option is useful to re-apply normalization parameters to other images or particular regions of interest. *Note: For a basic VBM analysis this is not needed.*

After setting all parameters, you will be able to save and run the module:

- File → Save Batch [optionally save your model and selections as a \*.m script file; the next time you can simply load this \*.m script file with “Load Batch”, and adjust / modify respective sections if necessary].
- File → Run Batch [the outcomes will be written to the same directory like the original data]. As per defaults, the outcomes will be the bias corrected normalized volumes (wm\*) and the tissue segments (i.e., the modulated normalized gray matter (m0wrp1\*) and white matter (m0wrp2) segments of each volume). If you selected the low-dimensional spatial normalization approach the modulated images will be named m0wp1\* for gray matter and m0wp2\* for white matter. All possible naming is summarized under “Naming convention of output files” (p. 17) and in the graphics window of SPM, when the SPM8 Toolbox is started.

---

## SECOND MODULE: DISPLAY ONE SLICE FOR ALL IMAGES

---

VBM8 → Check data quality → Display one slice for all images

Parameters:

- Volumes <-X → Select Files → [select the new files] → Done
  - Select the newly written data [e.g. the “wm\*” files, which are the normalized bias corrected volumes]. This tool will display one horizontal slice for each subject, thus giving a good overview if the segmentation and normalization procedures yielded reasonable results. For example, if the native volume had artifacts or if the native volumes had a wrong orientation, the results may look odd. Solutions: Use “Check Reg” from the SPM main menu to make sure that the native images have the same orientation like the MNI Template (“SPM → templates → T1”). Adjust if necessary using “Display” from the SPM main menu.
- Proportional scaling → [use defaults or modify]

- Check “yes”, if you display T1 volumes.

Show slice in mm → *[use defaults or modify]*

- This module displays horizontal slices. This default setting provides a good overview.

- File → Save Batch
- File → Run Batch [the outcomes will be displayed in SPM’s graphic window]

### THIRD MODULE: CHECK SAMPLE HOMOGENEITY USING COVARIANCE

VBM8 → Check data quality → Check sample homogeneity using covariance

Parameters:

- Volumes <-X → Select Files → *[select gray matter volumes]* → Done
  - Select the newly written data [e.g. the “m0wrp1\*” files, which are the normalized (wr) GM segments (p1) modulated for the non-linear components (m0)]. This tool visualizes the covariance between the volumes using a boxplot and covariance matrices. Thus, it will help identifying outliers. Any outlier should be carefully inspected for artifacts or pre-processing errors using “Check Reg” from the SPM main menu.
- Proportional scaling → *[use defaults or modify]*
  - Check “yes”, if you display T1 volumes.
- Show slice in mm → *[use defaults or modify]*
  - “0mm” means the center slice along the origin of the MNI template.
- Nuisance → *[enter nuisance variables if applicable]*
  - For each nuisance variable which you want to remove from the data prior to calculating the covariance, select “New: Nuisance” and enter a vector with the respective variable for each subject (e.g. age in years). All variables have to be entered in the same order as the respective volumes. You can also type “spm\_load” to upload a \*txt file with the covariates in the same order as the volumes.
- File → Save Batch
- File → Run Batch
  - A boxplot window and covariance matrices will open, which depict the covariance between the volumes; outliers can be displayed in SPM’s graphic window. The covariance matrix shows the covariance between all volumes. High covariance values mean that your data are more similar. The boxplot summarizes all covariance values for each subject and shows the

homogeneity of your sample. A small overall covariance in the boxplot not always means that this volume is an outlier or contains an artifact. If there are no artifacts in the image and if the image quality is reasonable you don't have to exclude this volume from the sample. This tool is intended to utilize the process of quality checking and there is no clear criteria defined to exclude a volume only based on the overall covariance value. However, volumes with an overall covariance below two standard deviations are indicated and should be checked very carefully.

---

#### FOURTH MODULE: SMOOTH

---

SPM menu → Smooth

Parameters:

- Images to Smooth <-X → Select Files → *[select grey matter volumes]* → Done
    - Select the newly written data [e.g. the “m0wrp1” files, which are the normalized (wr) grey matter segments (p1) modulated for the non-linear components (m0)].
  - FWHM → *[use defaults or modify]*
    - 8-12mm kernels are widely used for VBM. To use this setting select “edit value” and type “8 8 8” (or “12 12 12”, respectively) for a kernel with 8mm (with 12mm) FWHM.
  - Data Type → *[use defaults or modify]*
  - Filename Prefix → *[use defaults or modify]*
- 
- File → Save Batch *[this will save the parameters as \*.m script file]*
  - File → Run Batch *[the outcomes will be written to the same directory like the original data]*

## Building the statistical model

Although there are many potential designs offered in the 2nd-level analysis I recommend to use the “Full factorial” design because it covers most statistical designs. For cross-sectional VBM data you have usually 1..n samples and optionally covariates and nuisance parameters:

Number of factor levels	Number of covariates	Statistical Model
1	0	one-sample t-test
1	1	single regression
1	>1	multiple regression
2	0	two-sample t-test
>2	0	Anova
>1	>0	Ancova (for nuisance parameters) or Interaction (for covariates)

---

## TWO-SAMPLE T-TEST

---

SPM menu → Specify 2<sup>nd</sup>-level

Parameters:

- Directory <-X → Select Files → *[select the working directory for your analysis]* → Done
- Design → “Two-sample t-test”
  - Group 1 scans → Select Files → *[select the smoothed grey matter volumes for group 1; following this script these will be the “sm0wp1” files]* → Done
  - Group 2 scans → Select Files → *[select the smoothed grey matter volumes for group 2]* → Done
  - Independence → Yes
  - Variance → Equal or Unequal
  - Grand mean scaling → No
  - ANCOVA → No
- Covariates\*
- Masking

\*You could specify one or many covariates (i.e., partial out the variance of specific factors when looking at group differences)

- Covariates → New Covariate
- Vector <-X → enter the values of the covariates (e.g., age in years) in the same order as the respective file names or type “spm\_load” to upload a \*.txt file with the covariates in the same order as the volumes
- Name <-X → Specify Text (e.g., “age”)
- Interactions → None
- Centering → No centering

- Threshold Masking → Absolute → *[specify value (e.g., "0.1")]*
- Implicit Mask → Yes
- Explicit Mask → <None>
- Global Calculation → Omit
- Global Normalization
  - Overall grand mean scaling → No
- Normalization → None
- File → Save Batch [this will save the parameters as \*.m script file]
- File → Run Batch [this will create an "SPM.mat" file in your working directory]

---

## USING THE FULL FACTORIAL MODEL (FOR A 2X2 ANOVA)

---

SPM menu → Specify 2<sup>nd</sup>-level

Parameters:

- Directory <-X → Select Files → *[select the working directory for your analysis]* → Done
- Design → "Full Factorial"
  - Factors → "New: Factor; New: Factor"
    - Factor
      - Name → *[specify text (e.g., "sex")]*
      - Levels → 2
      - Independence → Yes
      - Variance → Equal or Unequal
      - Grand mean scaling → No
      - ANCOVA → No
    - Factor
      - Name → *[specify text (e.g., "handedness")]*
      - Levels → 2
      - Independence → Yes
      - Variance → Equal or Unequal
      - Grand mean scaling → No
      - ANCOVA → No
  - Specify Cells → "New: Cell; New: Cell; New: Cell; New: Cell"
    - Cell
      - Levels → *[specify text (e.g., "1 1")]*
      - Scans → *[select files (e.g., the smoothed GM volumes of the left-handed males)]*

Cell

- Levels → *[specify text (e.g., “1 2”)]*
- Scans → *[select files (e.g., the smoothed GM volumes of the right-handed males)]*

Cell

- Levels → *[specify text (e.g., “2 1”)]*
- Scans → *[select files (e.g., the smoothed GM volumes of the left-handed females)]*

Cell

- Levels → *[specify text (e.g., “2 2”)]*
- Scans → *[select files e.g., the smoothed GM volumes of the right-handed females)]*

- Covariates\*
- Masking
  - Threshold Masking → Absolute → *[specify value (e.g., “0.1”)]*
  - Implicit Mask → Yes
  - Explicit Mask → <None>
- Global Calculation → Omit
- Global Normalization
  - Overall grand mean scaling → No
- Normalization → None

- File → Save Batch [this will save the parameters as \*.m script file]
- File → Run Batch [this will create an “SPM.mat” file in your working directory]

---

## MULTIPLE REGRESSION (CORRELATION)

---

SPM menu → Specify 2<sup>nd</sup>-level

Parameters:

- Directory <-X → Select Files → *[select the directory for your analysis]* → Done
  - Design → “Multiple Regression”
    - Scans → *[select files (e.g., the smoothed GM volumes of all subjects)]* → Done
    - Covariates → “New: Covariate”
      - Covariate
        - Vector → *[enter the values in the same order as the respective file names of the smoothed GM images]*
        - Name → *[specify test (e.g., “age”)]*
        - Centering → No centering
        - Intercept → Include Intercept
  - Covariates\*
  - Masking
    - Threshold Masking → Absolute → *[specify value (e.g., “0.1”)]*
    - Implicit Mask → Yes
    - Explicit Mask → <None>
  - Global Calculation → Omit
  - Global Normalization
    - Overall grand mean scaling → No
  - Normalization → None
- File → Save Batch *[this will save the parameters as \*.m script file]*
  - File → Run Batch *[This will create an “SPM.mat” file in your selected folder]*

---

## USING THE FULL FACTORIAL MODEL (FOR AN INTERACTION)

---

SPM menu → Specify 2<sup>nd</sup>-level

Parameters:

- Directory <-X → Select Files → *[select the working directory for your analysis]* → Done
  - Design → “Full Factorial”
    - Factors → “New: Factor”
      - Factor
      - Name → *[specify text (e.g., “sex”)]*
      - Levels → 2
      - Independence → Yes
      - Variance → Equal or Unequal
      - Grand mean scaling → No
      - ANCOVA → No
    - Specify Cells → “New: Cell; New: Cell”
      - Cell
      - Levels → *[specify text (e.g., “1”)]*
      - Scans → *[select files (e.g., the smoothed GM volumes of the males)]*
      - Cell
      - Levels → *[specify text (e.g., “2”)]*
      - Scans → *[select files (e.g., the smoothed GM volumes of the females)]*
  - Covariates → “New: Covariate”
    - Covariate
      - Vector → *[enter the values in the same order as the respective file names of the smoothed GM images]*
      - Name → *[specify test (e.g., “age”)]*
      - Interactions → With Factor 1
      - Centering → No centering
  - Masking
    - Threshold Masking → Absolute → *[specify value (e.g., “0.1”)]*
    - Implicit Mask → Yes
    - Explicit Mask → <None>
  - Global Calculation → Omit
  - Global Normalization
    - Overall grand mean scaling → No
  - Normalization → None
- File → Save Batch [this will save the parameters as \*.m script file]
  - File → Run Batch [this will create an “SPM.mat” file in your working directory]

---

## ESTIMATING THE STATISTICAL MODEL

---

SPM menu → Estimate

Parameters:

- Select SPM.mat <-X → Select Files → *[select the SPM.mat which you just built]* → Done
- Method → “Classical”
- File → Save Batch
- File → Run Batch [This will create an “SPM.mat” file in your selected folder]

---

## DEFINING CONTRASTS

---

### Defining Contrasts:

SPM menu → Results → *[select the SPM.mat file]* → Done *(this opens the Contrast Manager)* → Define new contrast *(i.e., choose “t-contrast” or “F-contrast”; type the contrast name and specify the contrast by typing the respective numbers, as shown below):*

#### **T-contrasts:**

- a. Simple group difference
  - ⇒ Use SPM.mat from model **“2 sample T-test”**
    - For Group A > Group B: specify “1 -1”
    - For Group A < Group B: specify “-1 1”
- b. 2x2 ANOVA
  - ⇒ Use SPM.mat from model **“2x2 ANOVA”**
    - For left-handed males > right-handed males: specify “1 -1 0 0”
    - For left-handed females > right-handed females: specify “0 0 1 -1”
    - For left-handed males > left-handed females: specify “1 0 -1 0”
    - For right-handed males > right-handed females: specify “0 1 0 -1”
    - etc.
    - For males > females: specify “1 1 -1 -1”
    - For left-handers > right-handers: specify “1 -1 1 -1”
- c. Multiple Regression (Correlation)
  - ⇒ Use SPM.mat from model **“CORRELATION”**
    - For positive correlation: specify “1”

- For negative correlation: specify “-1”

d. Interaction

⇒ Use SPM.mat from model “**INTERACTION**”

- For regression slope Group A > Group B: specify “0 0 1 -1”
- For regression slope Group A < Group B: specify “0 0 -1 1”

→ Done

### **F-contrasts:**

If you would like to use the old SPM2 F-contrast “Effects of interest” the respective contrast vector is:

$$eye(n)-1/n$$

where  $n$  is the number of columns of interest. This F-contrast is often helpful for plotting parameter estimates of effects of interest.

### **Getting Results:**

SPM menu → Results → *[select a contrast from Contrast Manager]* → Done

- Mask with other contrasts → No
- Title for comparison: *[use the pre-defined name from the Contrast Manager or change it]*
- P value adjustment to:
  - None (uncorrected for multiple comparisons), set threshold to 0.001
  - FDR (false discovery rate), set threshold to 0.05, etc.
  - FWE (family-wise error), set threshold to 0.05, etc.
- Extent threshold: [either use “none” or specify the number of voxels<sup>2</sup>]

---

<sup>2</sup> In order to *empirically* determine the extent threshold (rather than saying 100 voxels or 500 voxels, which is completely arbitrary), simply run this first without specifying an extent threshold. This will give you an output (i.e., the standard SPM glass brain with significant effects). When you click “Table” (SPM main menu) you will get a table with all relevant values (MNI coordinates, p-values, cluster size etc). Below the table you will find additional information, such as “Expected Number of Voxels per Cluster”. Remember this number (this is your empirically determined extent threshold). Re-run SPM → Results etc. and specify this number when asked for the “Extent Threshold”. There is also a hidden option in “VBM8 → Data presentation → Threshold and transform spmT-maps” to define the extent threshold in terms of a p-value or to use the “Expected Number of Voxels per Cluster”.

## ***Additional information on native, normalized and modulated volumes***

When preprocessing the images (see “First Module: Estimate and write”, on pages 5-6), the decision about the normalization parameters will determine the interpretation of the analysis outcomes:

“**Native space**” produces tissue class images in spatial correspondence to the original data. Although this could be useful for estimating global tissue volumes (e.g.,  $GM+WM+CSF=TBV$ ) it is not suitable to conduct VBM analyses due to the missing voxel-wise correspondence across brains). Of note, if one is interested in these global tissue volumes in native space (“raw values”), it won’t be necessary to actually output the tissue class images in native space. The “Estimate and write”-function automatically generates a text file for each subject (\*\_seg8.txt), which contains the raw values for GM, WM, and CSF. The subject-specific values can be combined (i.e., integrated into a single text file) by using the function “Calculate raw volumes for GM/WM/CSF”: VBM8 → Tools → Calculate raw volumes for GM/WM/CSF

“**Normalized**” produces tissue class images in spatial correspondence to the template. This is useful for VBM analyses (e.g., “concentration” of gray matter; Good et al. 2001; Neuroimage).

“**Modulated normalized**” gives two different options:

- **Affine+non-linear** produces tissue class images in alignment with the template, but multiplies (“modulates”) the voxel values by the Jacobian determinant (i.e., linear and non-linear components) derived from the spatial normalization. This is useful for VBM analyses and allows comparing the *absolute amount of tissue* (e.g., “volume” of gray matter; Good et al. 2001; Neuroimage).
- **Non-linear only** produces tissue class images in alignment with the template, but multiplies the voxel values by the non-linear components only. This is useful for VBM analyses and allows comparing the *absolute amount of tissue corrected for individual brain sizes*. Of note, this option is similar to using “Affine+non-linear” (see above) in combination with “global normalization” (when later building the statistical model using the traditional PET designs). That is, when building the statistics, one would specify “Global normalization” → “Overall grand mean scaling – No” → “Normalization – Proportional”. It is also similar to using “Affine+non-linear” (see above) and including the numeric brain volume (as given in the \*\_seg8.txt file for each subject) as covariate (when later building the statistical model). Although all 3 approaches allow comparing tissue volumes while correcting for individual brain size, it is recommended to use the option “non-linear only” as it applies the correction directly to the data, rather than to the statistical model.

For further explanation see also:

<http://dbm.neuro.uni-jena.de/vbm/segmentation/modulation>

## ***Naming convention of output files***

### segmented images:

m[0]w[r]p[0123]\*  
m - modulated  
m0 - modulated non-linear only  
w - warped  
r - dartel warped  
p - segmented  
0 - PVE label  
1 - GM  
2 - WM  
3 - CSF  
\_affine - affine registered only

### bias corrected images:

wm[r]\*  
m - bias corrected  
w - warped  
r - dartel warped

### estimated raw volumes:

pxxx\_seg.txt

## ***Technical information***

This toolbox is an extension of the “New Segment Toolbox” in SPM8, but uses a completely different segmentation approach.<sup>3</sup>

1. The segmentation approach is based on an adaptive **Maximum A Posterior (MAP) technique** without the need for *a priori* information about tissue probabilities. That is, the Tissue Probability Maps are not used constantly in the sense of the classical unified segmentation approach, but just for spatial normalization<sup>3</sup>. The following MAP estimation is adaptive in the sense that local variations of the parameters (i.e., means and variance) are modelled as slowly varying spatial functions (Rajapakse et al. 1997). This not only accounts for intensity inhomogeneities but also for other local variations of intensity.
2. Additionally, the segmentation approach uses a **Partial Volume Estimation (PVE)** with a simplified mixed model of at most two tissue types (Tohka et al. 2004). We start with an initial segmentation into three pure classes: gray matter (GM), white matter (WM), and cerebrospinal fluid (CSF) based on the above described MAP estimation. The initial segmentation is followed by a PVE of two additional mixed classes: GM-WM and GM-CSF. This results in an estimation of the amount (or fraction) of each pure tissue type present in every voxel (as single voxels – given by their size – probably contain more than one tissue type) and thus provides a more accurate segmentation.
3. Furthermore, we apply **two denoising methods**. The first method is an optimized block-wise non-local means (NLM) denoising filter (Coupe et al. 2008). This filter will remove noise while preserving edges and is implemented as preprocessing step. The second method is a classical Markov Random Field (MRF) approach, which incorporates spatial prior information of adjacent voxels into the segmentation estimation (Rajapakse et al. 1997).
4. Another important extension to the SPM8 segmentation is the **integration of the Dartel normalisation** (Ashburner 2007) into the toolbox. If high-dimensional spatial normalisation is

---

<sup>3</sup> The classic SPM8 segmentation is still used in addition, but only to initially remove non-brain tissue from the image.

chosen, an already existing Dartel template in MNI space will be used. This template was derived from 550 healthy control subjects of the IXI-database (<http://www.brain-development.org>) and is provided in MNI space<sup>4</sup> for six different iteration steps of Dartel normalisation. Thus, for the majority of studies the creation of sample-specific Dartel templates is not necessary anymore<sup>5</sup>.

<sup>4</sup> Thus, no additional MNI normalization is necessary.

<sup>5</sup> For studies investigating data of children I still recommend creating a customized Dartel template. Of note, for this option a representative sample with a sufficient number of subjects is required (n>50-100). Alternatively, if a sufficient sample size cannot be achieved, the low-dimensional SPM8 normalization approach combined with customized Tissue Probability Maps (e.g. from the TOM8 toolbox) can be selected.
